GPkit is a Python package for defining and manipulating geometric programming (GP) models.

Our hopes are to bring the mathematics of Geometric Programming into the engineering design process in a disciplined and collaborative way, and to encourage research with and on GPs by providing an easily extensible object-oriented framework.

GPkit abstracts away the backend solver so that users can work directly with engineering equations and optimization concepts. Supported solvers are MOSEK and CVXOPT.

Join our mailing list and/or chatroom for support and examples.

## CHAPTER 1

### Geometric Programming 101

### 1.1 What is a GP?

A Geometric Program (GP) is a type of non-linear optimization problem whose objective and constraints have a particular form.

The decision variables must be strictly positive (non-zero, non-negative) quantities. This is a good fit for engineering design equations (which are often constructed to have only positive quantities), but any model with variables of unknown sign (such as forces and velocities without a predefined direction) may be difficult to express in a GP. Such models might be better expressed as *Signomials*.

More precisely, GP objectives and inequalities are formed out of *monomials* and *posynomials*. In the context of GP, a monomial is defined as:

$$f(x) = cx_1^{a_1} x_2^{a_2} ... x_n^{a_n}$$

where c is a positive constant,  $x_{1..n}$  are decision variables, and  $a_{1..n}$  are real exponents. For example, taking x, y and z to be positive variables, the expressions

$$7x 4xy^2z \frac{2x}{y^2z^{0.3}} \sqrt{2xy}$$

are all monomials. Building on this, a posynomial is defined as a sum of monomials:

$$g(x) = \sum_{k=1}^{K} c_k x_1^{a_1 k} x_2^{a_2 k} \dots x_n^{a_n k}$$

For example, the expressions

$$x^{2} + 2xy + 1$$
  $7xy + 0.4(yz)^{-1/3}$   $0.56 + \frac{x^{0.7}}{yz}$ 

are all posynomials. Alternatively, monomials can be defined as the subset of posynomials having only one term. Using  $f_i$  to represent a monomial and  $g_i$  to represent a posynomial, a GP in standard form is

written as:

minimize 
$$g_0(x)$$
  
subject to  $f_i(x) = 1, \quad i = 1, ...., m$   
 $g_i(x) \le 1, \quad i = 1, ...., n$ 

Boyd et. al. give the following example of a GP in standard form:

$$\begin{array}{ll} \text{minimize} & x^{-1}y^{-1/2}z^{-1} + 2.3xz + 4xyz\\ \text{subject to} & (1/3)x^{-2}y^{-2} + (4/3)y^{1/2}z^{-1} \leq 1\\ & x + 2y + 3z \leq 1\\ & (1/2)xy = 1 \end{array}$$

## 1.2 Why are GPs special?

Geometric programs have several powerful properties:

- 1. Unlike most non-linear optimization problems, large GPs can be solved extremely quickly.
- 2. If there exists an optimal solution to a GP, it is guaranteed to be globally optimal.
- 3. Modern GP solvers require **no initial guesses** or tuning of solver parameters.

These properties arise because GPs become *convex optimization problems* via a logarithmic transformation. In addition to their mathematical benefits, recent research has shown that many practical problems can be formulated as GPs or closely approximated as GPs.

## 1.3 What are Signomials / Signomial Programs?

When the coefficients in a posynomial are allowed to be negative (but the variables stay strictly positive), that is called a Signomial.

A Signomial Program has signomial constraints. While they cannot be solved as quickly or to global optima, because they build on the structure of a GP they can often be solved more quickly than a generic nonlinear program. More information can be found under *Signomial Programming*.

### 1.4 Where can I learn more?

To learn more about GPs, refer to the following resources:

- A tutorial on geometric programming, by S. Boyd, S.J. Kim, L. Vandenberghe, and A. Hassibi.
- Convex optimization, by S. Boyd and L. Vandenberghe.
- Geometric Programming for Aircraft Design Optimization, Hoburg, Abbeel 2014

## CHAPTER 2

### Installation

- 1. If you are on Mac or Windows, we recommend installing Anaconda. Alternatively, install pip and create a virtual environment.
- 2. (optional) Install the MOSEK solver as directed below
- 3. Run pip install gpkit in the appropriate terminal or command prompt.
- 4. Open a Python prompt and run import gpkit to finish installation and run unit tests.

If you encounter any bugs please email gpkit@mit.edu or raise a GitHub issue.

## 2.1 Installing MOSEK

GPkit interfaces with two off the shelf solvers: cvxopt, and MOSEK. Cvxopt is open source and installed by default; MOSEK requires a commercial licence or (free) academic license.

#### Mac OS X

- If which gcc does not return anything, install the Apple Command Line Tools.
- Download MOSEK 8, then:
  - Move the mosek folder to your home directory
  - Follow these steps for Mac.
  - Request an academic license file and put it in ~/mosek/

### Linux

- Download MOSEK 8, then:
  - Move the mosek folder to your home directory
  - Follow these steps for Linux.
  - Request an academic license file and put it in ~/mosek/

#### Windows

- Download MOSEK 8, then:
  - Follow these steps for Windows.
  - Request an academic license file and put it in
    C:\Users\(your\_username)\mosek\
  - Make sure gcc is on your system path.
    - \* To do this, type gcc into a command prompt.
    - \* If you get executable not found, then install the 64-bit version (x86\_64 installer architecture dropdown option) with GCC version 6.4.0 or older of mingw.
    - \* In an Anaconda command prompt (or equivalent), run cd C:\Program Files\mingw-w64\x86\_64-6.4.0-posix-seh-rt\_v5-rev0\ (or whatever corresponds to the correct installation directory; note that if mingw is in Program Files (x86) instead of Program Files you've installed the 32-bit version by mistake)
    - \* Run mingw-w64 to add it to your executable path. For step 3 of the install process you'll need to run pip install gpkit from this prompt.

### 2.2 Debugging your installation

You may need to rebuild GPkit if any of the following occur:

- You install MOSEK after installing GPkit
- You see Could not load settings file. when importing GPkit, or
- Could not load MOSEK library: ImportError('expopt.so not found.')

To rebuild GPkit run python -c "from qpkit.build import rebuild; rebuild()".

### If that doesn't solve your issue then try the following:

- pip uninstall gpkit
- pip install --no-cache-dir --no-deps gpkit
- python -c "import qpkit.tests; qpkit.tests.run()"
- If any tests fail, please email gpkit@mit.edu or raise a GitHub issue.

## 2.3 Bleeding-edge installations

Active developers may wish to install the latest GPkit directly from Github. To do so,

- 1. pip uninstall gpkit to uninstall your existing GPkit.
- 2. git clone https://github.com/convexengineering/gpkit.git
- 3. pip install -e gpkit to install that directory as your environment-wide GPkit.
- 4. cd ..; python -c "import gpkit.tests; gpkit.tests.run()" to test your installation from a non-local directory.

## CHAPTER 3

**Getting Started** 

GPkit is a Python package, so we assume basic familiarity with Python: if you're new to Python we recommend you take a look at Learn Python.

Otherwise, install GPkit and import away:

```
from gpkit import Variable, VectorVariable, Model
from gpkit.nomials import Monomial, Posynomial, PosynomialInequality
```

## 3.1 Declaring Variables

Instances of the Variable class represent scalar variables. They create a VarKey to store the variable's name, units, a description, and value (if the Variable is to be held constant), as well as other metadata.

### 3.1.1 Free Variables

```
# Declare a variable, x
x = Variable("x")

# Declare a variable, y, with units of meters
y = Variable("y", "m")

# Declare a variable, z, with units of meters, and a description
z = Variable("z", "m", "A variable called z with units of meters")
```

#### 3.1.2 Fixed Variables

To declare a variable with a constant value, use the Variable class, as above, but put a number before the units:

```
rho = Variable("rho", 1.225, "kg/m^3", "Density of air at sea level")
```

In the example above, the key name "\rho" is for LaTeX printing (described later). The unit and description arguments are optional.

```
#Declare pi equal to 3.14
pi = Variable("pi", 3.14159, "-", constant=True)
```

### 3.1.3 Vector Variables

Vector variables are represented by the VectorVariable class. The first argument is the length of the vector. All other inputs follow those of the Variable class.

```
# Declare a 3-element vector variable "x" with units of "m"
x = VectorVariable(3, "x", "m", "Cube corner coordinates")
x_min = VectorVariable(3, "x", [1, 2, 3], "m", "Cube corner minimum")
```

## 3.2 Creating Monomials and Posynomials

Monomial and posynomial expressions can be created using mathematical operations on variables.

```
# create a Monomial term xy^2/z
x = Variable("x")
y = Variable("y")
z = Variable("z")
m = x * y**2 / z
assert isinstance(m, Monomial)
```

```
# create a Posynomial expression x + xy^2
x = Variable("x")
y = Variable("y")
p = x + x * y**2
assert isinstance(p, Posynomial)
```

## 3.3 Declaring Constraints

Constraint objects represent constraints of the form Monomial >= Posynomial or Monomial == Monomial (which are the forms required for GP-compatibility).

Note that constraints must be formed using  $\langle =, >=, \text{ or } == \text{ operators, not } < \text{ or } >$ .

```
# consider a block with dimensions x, y, z less than 1
# constrain surface area less than 1.0 m^2
x = Variable("x", "m")
y = Variable("y", "m")
z = Variable("z", "m")
S = Variable("S", 1.0, "m^2")
c = (2*x*y + 2*x*z + 2*y*z <= S)
assert isinstance(c, PosynomialInequality)</pre>
```

## 3.4 Formulating a Model

The Model class represents an optimization problem. To create one, pass an objective and list of Constraints.

By convention, the objective is the function to be *minimized*. If you wish to *maximize* a function, take its reciprocal. For example, the code below creates an objective which, when minimized, will maximize x \* y \* z.

## 3.5 Solving the Model

When solving the model you can change the level of information that gets printed to the screen with the verbosity setting. A verbosity of 1 (the default) prints warnings and timing; a verbosity of 2 prints solver output, and a verbosity of 0 prints nothing.

```
sol = m.solve(verbosity=0)
```

## 3.6 Printing Results

The solution object can represent itself as a table:

```
print(sol.table())
```

We can also print the optimal value and solved variables individually.

```
print("The optimal value is %s." % sol["cost"])
```

```
The optimal value is 15.5884619886.
The x dimension is 0.5774 meter.
The y dimension is 0.2887 meter.
```

### 3.7 Sensitivities and Dual Variables

When a GP is solved, the solver returns not just the optimal value for the problem's variables (known as the "primal solution") but also the effect that relaxing each constraint would have on the overall objective (the "dual solution").

From the dual solution GPkit computes the sensitivities for every fixed variable in the problem. This can be quite useful for seeing which constraints are most crucial, and prioritizing remodeling and assumption-checking.

### 3.7.1 Using Variable Sensitivities

Fixed variable sensitivities can be accessed from a SolutionArray's ["sensitivities"]["variables"] dict, as in this example:

```
x = Variable("x")
x_min = Variable("x_{min}", 2)
sol = Model(x, [x_min <= x]).solve()
sens_x_min = sol["sensitivities"]["variables"][x_min]</pre>
```

These sensitivities are actually log derivatives  $(\frac{d\log(y)}{d\log(x)})$ ; whereas a regular derivative is a tangent line, these are tangent monomials, so the 1 above indicates that  $x_{\min}$  has a linear relation with the objective. This is confirmed by a further example:

```
x = Variable("x")
x_squared_min = Variable("x^2_{min}", 2)
sol = Model(x, [x_squared_min <= x**2]).solve()
sens_x_min = sol["sensitivities"]["variables"][x_squared_min]</pre>
```

## CHAPTER 4

## **Debugging Models**

A number of errors and warnings may be raised when attempting to solve a model. A model may be primal infeasible: there is no possible solution that satisfies all constraints. A model may be dual infeasible: the optimal value of one or more variables is 0 or infinity (negative and positive infinity in logspace).

For a GP model that does not solve, solvers may be able to prove its primal or dual infeasibility, or may return an unknown status.

GPkit contains several tools for diagnosing which constraints and variables might be causing infeasibility. The first thing to do with a model m that won't solve is to run m. debug(), which will search for changes that would make the model feasible:

```
"Debug examples"
from gpkit import Variable, Model, units
x = Variable("x", "ft")
x_min = Variable("x_min", 2, "ft")
x_max = Variable("x_max", 1, "ft")
y = Variable("y", "volts")
m = Model(x/y, [x \le x_max, x \ge x_min])
m.debug()
print("# Now let's try a model unsolvable with relaxed constants\n")
m2 = Model(x, [x \le units("inch"), x \ge units("yard")])
m2.debug()
print("# And one that's only unbounded\n")
# the value of x_min was used up in the previous model!
x_min = Variable("x_min", 2, "ft")
m3 = Model(x/y, [x >= x_min])
m3.debug()
```

```
< DEBUGGING >
> Trying with bounded variables and relaxed constants:
Solves with these variables bounded:
sensitive to upper bound: y
  value near upper bound: y
and these constants relaxed:
 x_min [ft]: relaxed from 2 to 1
>> Success!
# Now let's try a model unsolvable with relaxed constants
> Trying with bounded variables and relaxed constants:
>> Failure.
> Trying with relaxed constraints:
Solves with these constraints relaxed:
   1: 3500% relaxed, from x [ft] >= 1 [yd]
                    to 36 \cdot x [ft] >= 1 [yd]
>> Success!
# And one that's only unbounded
< DEBUGGING >
> Trying with bounded variables and relaxed constants:
Solves with these variables bounded:
sensitive to upper bound: y
  value near upper bound: y
>> Success!
```

Note that certain modeling errors (such as omitting or forgetting a constraint) may be difficult to diagnose from this output.

## 4.1 Potential errors and warnings

- RuntimeWarning: final status of solver 'mosek' was 'DUAL\_INFEAS\_CER', not 'optima
  - The solver found a certificate of dual infeasibility: the optimal value of one or more variables is 0 or infinity. See *Dual Infeasibility* below for debugging advice.
- RuntimeWarning: final status of solver 'mosek' was 'PRIM\_INFEAS\_CER', not 'optima
  - The solver found a certificate of primal infeasibility: no possible solution satisfies all constraints. See *Primal Infeasibility* below for debugging advice.
- RuntimeWarning: final status of solver 'cvxopt' was 'unknown', not 'optimal' or Run
  - The solver could not solve the model or find a certificate of infeasibility. This may indicate a dual infeasible model, a primal infeasible model, or other numerical issues. Try

debugging with the techniques in *Dual* and *Primal Infeasibility* below.

- RuntimeWarning: Primal solution violates constraint: 1.0000149786 is greater tha
  - this warning indicates that the solver-returned solution violates a constraint of the model, likely because the solver's tolerance for a final solution exceeds GPkit's tolerance during solution checking. This is sometimes seen in dual infeasible models, see *Dual Infeasibility* below. If you run into this, please note on this GitHub issue your solver and operating system.
- RuntimeWarning: Dual cost nan does not match primal cost 1.00122315152
  - Similarly to the above, this warning may be seen in dual infeasible models, see *Dual Infeasibility* below.

## 4.2 Dual Infeasibility

In some cases a model will not solve because the optimal value of one or more variables is 0 or infinity (negative or positive infinity in logspace). Such a problem is *dual infeasible* because the GP's dual problem, which determines the optimal values of the sensitivites, does not have any feasible solution. If the solver can prove that the dual is infeasible, it will return a dual infeasibility certificate. Otherwise, it may finish with a solution status of unknown.

gpkit.constraints.bounded.Bounded is a simple tool that can be used to detect unbounded variables and get dual infeasible models to solve by adding extremely large upper bounds and extremely small lower bounds to all variables in a ConstraintSet.

When a model with a Bounded ConstraintSet is solved, it checks whether any variables slid off to the bounds, notes this in the solution dictionary and prints a warning (if verbosity is greater than 0).

For example, Mosek returns DUAL\_INFEAS\_CER when attempting to solve the following model:

```
"Demonstrate a trivial unbounded variable"
from gpkit import Variable, Model
from gpkit.constraints.bounded import Bounded

x = Variable("x")

constraints = [x >= 1]

m = Model(1/x, constraints) # MOSEK returns DUAL_INFEAS_CER on .solve()
m = Model(1/x, Bounded(constraints))
# by default, prints bounds warning during solve
sol = m.solve(verbosity=0)
print(sol.summary())
# but they can also be accessed from the solution:
assert (sol["boundedness"]["value near upper bound"])
== sol["boundedness"]["sensitive to upper bound"])
```

Upon viewing the printed output,

```
Solves with these variables bounded:
sensitive to upper bound: x
value near upper bound: x
```

The problem, unsurprisingly, is that the cost 1/x has no lower bound because x has no upper bound.

For details read the Bounded docstring.

### 4.3 Primal Infeasibility

A model is primal infeasible when there is no possible solution that satisfies all constraints. A simple example is presented below.

```
"A simple primal infeasible example"
from gpkit import Variable, Model

x = Variable("x")
y = Variable("y")

m = Model(x*y, [
    x >= 1,
    y >= 2,
    x*y >= 0.5,
    x*y <= 1.5
])

# raises UnknownInfeasible on cvxopt, PrimalInfeasible on mosek
# m.solve()</pre>
```

It is not possible for x \* y to be less than 1.5 while x is greater than 1 and y is greater than 2.

A common bug in large models that use substitutions is to substitute overly constraining values in for variables that make the model primal infeasible. An example of this is given below.

```
"Another simple primal infeasible example"
from gpkit import Variable, Model

x = Variable("x")
y = Variable("y", 2)

constraints = [
    x >= 1,
    0.5 <= x*y,
    x*y <= 1.5</pre>
```

```
objective = x*y
m = Model(objective, constraints)

# raises UnknownInfeasible on cvxopt and PrimalInfeasible on mosek
# m.solve()
```

Since y is now set to 2 and x can be no less than 1, it is again impossible for x\*y to be less than 1.5 and the model is primal infeasible. If y was instead set to 1, the model would be feasible and the cost would be 1.

### 4.3.1 Relaxation

If you suspect your model is primal infeasible, you can find the nearest primal feasible version of it by relaxing constraints: either relaxing all constraints by the smallest number possible (that is, dividing the less-than side of every constraint by the same number), relaxing each constraint by its own number and minimizing the product of those numbers, or changing each constant by the smallest total percentage possible.

```
"Relaxation examples"
from gpkit import Variable, Model
x = Variable("x")
x_min = Variable("x_min", 2)
x_max = Variable("x_max", 1)
m = Model(x, [x \le x_max, x \ge x_min])
print("Original model")
print("======")
print (m)
print("")
# m.solve() # raises a RuntimeWarning!
print("With constraints relaxed equally")
print ("======"")
from gpkit.constraints.relax import ConstraintsRelaxedEqually
allrelaxed = ConstraintsRelaxedEqually(m)
mr1 = Model(allrelaxed.relaxvar, allrelaxed)
print (mr1)
print(mr1.solve(verbosity=0).table()) # solves with an x of 1.414
print("")
print("With constraints relaxed individually")
print ("======="")
from gpkit.constraints.relax import ConstraintsRelaxed
constraintsrelaxed = ConstraintsRelaxed(m)
mr2 = Model(constraintsrelaxed.relaxvars.prod() * m.cost**0.01,
           # add a bit of the original cost in
           constraintsrelaxed)
print (mr2)

### Visualization and Interaction

## 5.1 Sankey Diagrams

### 5.1.1 Requirements

- Jupyter Notebook
- · ipysankeywidget

### 5.1.2 Example

Code in this section uses the CE solar model

```
from solar import *
Vehicle = Aircraft(Npod=1, sp = False)
M = Mission(Vehicle, latitude=[20])
M.cost = M[M.aircraft.Wtotal]
sol = M.solve()

from gpkit.interactive.sankey import Sankey
Sankey(M).diagram(M.aircraft.Wtotal)
```

```
(objective) adds +1 to the sensitivity of Wtotal_Aircraft
(objective) is Wtotal_Aircraft [lbf]

adds +0.0075 to the overall sensitivity of Wtotal_Aircraft
is Wtotal_Aircraft <= 0.5*CL_Mission/Climb/AircraftDrag/WingAero_(0,)*S_

→Aircraft/Wing/Planform.2*V_Mission/Climb_(0, 0)**2*rho_Mission/Climb_(0, 0)

adds +0.0117 to the overall sensitivity of Wtotal_Aircraft
is Wtotal_Aircraft <= 0.5*CL_Mission/Climb/AircraftDrag/WingAero_(1,)*S_

→Aircraft/Wing/Planform.2*V_Mission/Climb_(0, 1)**2*rho_Mission/Commission(Commission) (Accommission) (Ac
```

### 5.1.3 Explanation

Sankey diagrams can be used to visualize sensitivity structure in a model. A blue flow from a constraint to its parent indicates that the sensitivity of the chosen variable (or of making the constraint easier, if no variable is given) is negative; that is, the objective of the overall model would improve if that variable's value were increased *in that constraint alone*. Red indicates a positive sensitivity: the objective and the the constraint 'want' that variable's value decreased. Gray flows indicate a sensitivity whose absolute value is below 1e-7, i.e. a constraint that is inactive for that variable. Where equal red and blue flows meet, they cancel each other out to gray.

### 5.1.4 Usage

#### **Variables**

In a Sankey diagram of a variable, the variable is on the left with its final sensitivity; to the right of it are all constraints that variable is in.

#### Free

Free variables have an overall sensitivity of 0, so this visualization shows how the various pressures on that variable in all its constraints cancel each other out; this can get quite complex, as in this diagram of the pressures on wingspan:

```
Sankey(M).diagram(M.aircraft.b)
```

#### **Fixed**

Fixed variables can have a nonzero overall sensitivity. Sankey diagrams can how that sensitivity comes together:

```
Sankey(M).diagram(M['vgust'])
```

#### **Equivalent Variables**

If any variables are equal to the diagram's variable (modulo some constant factor; e.g.  $2 \times x == y$  counts for this, as does  $2 \times x <= y$  if the constraint is sensitive), they are found and plotted at the same time, and all shown on the left. The constraints responsible for this are shown next to their labels.

```
Sankey(M).sorted_by('constraints', 11)
```

#### **Models**

When created without a variable, the diagram shows the sensitivity of every named model to becoming locally easier. Because derivatives are additive, these sensitivities are too: a model's sensitivity is equal to the sum of its constraints' sensitivities. Gray lines in this diagram indicate models without any tight constraints.

### 5.1.5 Syntax

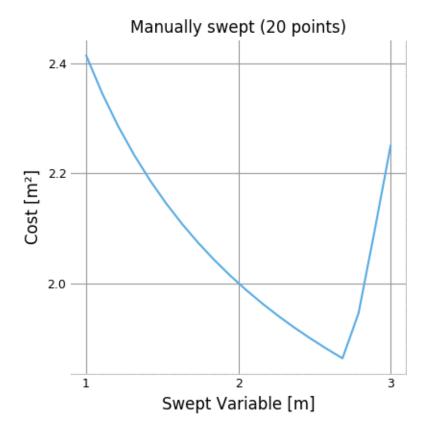

| Code   | Result  |  |
|--|---|--|
| s = Sankey(M)  | Creates Sankey object of a given model                                    |  |
| s.diagram(vars)  | Creates the diagram in a way Jupyter knows how to present                 |  |
| d = s.diagram()  | Don't do this! Captures output, preventing Jupyter from seeing it.        |  |
| s.diagram(width=.                                      | Sets width in pixels. Same for height.                                    |  |
| )  |   |  |
| s.diagram(left=  | Sets top margin in pixels. Same for right, top. bottom. Use if the left-  |  |
| .)   | hand text is being cut off.   |  |
| S.   | Shows the variable / top constraint on the right instead of the left.     |  |
| diagram(flowright=T                                    | rue)  |  |
| S.   | Creates diagram of the variable with the largest single constraint sensi- |  |
| sorted_by("maxflow"                                    | rted_by("maxflow", tivity. (change the 0 index to go down the list)       |  |
| 0)   |   |  |
| S.   | Creates diagram of the variable that's in the most constraints. (change   |  |
| sorted_by ("constrainthe"), index to go down the list) |   |  |
| 0)   |   |  |

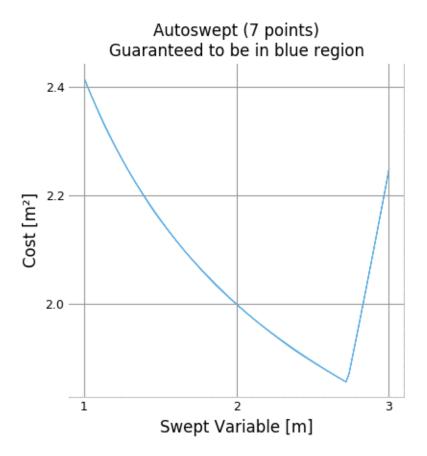

## 5.2 Plotting a 1D Sweep

Methods exist to facilitate creating, solving, and plotting the results of a single-variable sweep (see *Sweeps* for details). Example usage is as follows:

```
"Demonstrates manual and auto sweeping and plotting"
import matplotlib as mpl
mpl.use('Agg')
# comment out the lines above to show figures in a window
import numpy as np
from gpkit import Model, Variable, units
from gpkit.constraints.tight import Tight
x = Variable("x", "m", "Swept Variable")
y = Variable("y", "m^2", "Cost")
m = Model(y, [
    y >= (x/2)**-0.5 * units.m**2.5 + 1*units.m**2,
   Tight([y >= (x/2)**2])
# arguments are: model, swept: values, posnomial for y-axis
sol = m.sweep({x: np.linspace(1, 3, 20)}, verbosity=0)
f, ax = sol.plot(y)
ax.set_title("Manually swept (20 points)")
```

Which results in:

## CHAPTER 6

## **Building Complex Models**

## 6.1 Checking for result changes

Tracking the effects of changes to complex models can get out of hand; we recommend saving solutions with sol.save(), then checking that new solutions are almost equivalent with soll.almost\_equal(sol2) and/or print(soll.diff(sol2)), as shown below.

```
"Example code for solution saving and differencing."
import pickle
from gpkit import Model, Variable
# build model (dummy)
# decision variable
x = Variable("x")
y = Variable("y")
# objective and constraints
objective = 0.23 + x/y \# minimize x and y
constraints = [x + y \le 5, x \ge 1, y \ge 2]
# create model
m = Model(objective, constraints)
# solve the model
sol = m.solve()
# save the current state of the model
sol.save("last_verified.sol")
# uncomment the line below to verify a new model
last_verified_sol = pickle.load(open("last_verified.sol", mode="rb"))
if not sol.almost_equal(last_verified_sol, reltol=1e-3):
    print(last_verified_sol.diff(sol))
```

```
# Note you can replace the last three lines above with
# print(sol.diff("last_verified.sol"))
# if you don't mind doing the diff in that direction.
```

You can also check differences between swept solutions, or between a point solution and a sweep.

### 6.2 Inheriting from Model

GPkit encourages an object-oriented modeling approach, where the modeler creates objects that inherit from Model to break large systems down into subsystems and analysis domains. The benefits of this approach include modularity, reusability, and the ability to more closely follow mental models of system hierarchy. For example: two different models for a simple beam, designed by different modelers, should be able to be used interchangeably inside another subsystem (such as an aircraft wing) without either modeler having to write specifically with that use in mind.

When you create a class that inherits from Model, write a .setup() method to create the model's variables and return its constraints. GPkit.Model.\_\_init\_\_ will call that method and automatically add your model's name and unique ID to any created variables.

Variables created in a setup method are added to the model even if they are not present in any constraints. This allows for simplistic 'template' models, which assume constant values for parameters and can grow incrementally in complexity as those variables are freed.

At the end of this page a detailed example shows this technique in practice.

## 6.3 Accessing Variables in Models

GPkit provides several ways to access a Variable in a Model (or ConstraintSet):

- using Model.variables\_byname(key). This returns all Variables in the Model, as well as in any submodels, that match the key.
- using Model.\_\_getitem\_\_. Model [key] returns the only variable matching the key, even if the match occurs in a submodel. If multiple variables match the key, an error is raised.

These methods are illustrated in the following example.

```
"Demo of accessing variables in models"

from gpkit import Model, Variable

class Battery(Model):
    """A simple battery

    Upper Unbounded
    -----
    m

Lower Unbounded
    -----
E
```

```
def setup(self):
       h = Variable("h", 200, "Wh/kg", "specific energy")
       E = self.E = Variable("E", "MJ", "stored energy")
       m = self.m = Variable("m", "lb", "battery mass")
        return [E <= m*h]
class Motor(Model):
    """Electric motor
   Upper Unbounded
   Lower Unbounded
   Pmax
    def setup(self):
       m = self.m = Variable("m", "lb", "motor mass")
        f = Variable("f", 20, "lb/hp", "mass per unit power")
       Pmax = self.Pmax = Variable("P_{max}", "hp", "max output power")
       return [m >= f*Pmax]
class PowerSystem(Model):
    """A battery powering a motor
    Upper Unbounded
   Lower Unbounded
   E, Pmax
   def setup(self):
       battery, motor = Battery(), Motor()
       components = [battery, motor]
       m = self.m = Variable("m", "lb", "mass")
       self.E = battery.E
       self.Pmax = motor.Pmax
        return [components,
                m >= sum(comp.m for comp in components)]
PS = PowerSystem()
print("Getting the only var 'E': %s" % PS["E"])
print("The top-level var 'm': %s" % PS.m)
print("All the variables 'm': %s" % PS.variables_byname("m"))
```

```
Getting the only var 'E': PowerSystem.Battery.E [MJ]
The top-level var 'm': PowerSystem.m [lb]
All the variables 'm': [gpkit.Variable(PowerSystem.Battery.m [lb]), gpkit.

Variable(PowerSystem.Motor.m [lb]), gpkit.Variable(PowerSystem.m [lb])]
```

### 6.4 Vectorization

gpkit. Vectorize creates an environment in which Variables are created with an additional dimension:

```
"Example Vectorize usage, from gpkit/tests/t_vars.py"
from gpkit import Variable, Vectorize, VectorVariable

with Vectorize(3):
    with Vectorize(5):
        y = Variable("y")
        x = VectorVariable(2, "x")
    z = VectorVariable(7, "z")

assert(y.shape == (5, 3))
assert(x.shape == (2, 5, 3))
assert(z.shape == (7, 3))
```

This allows models written with scalar constraints to be created with vector constraints:

```
"Vectorization demonstration"
from gpkit import Model, Variable, Vectorize
class Test (Model):
    """A simple scalar model
    Upper Unbounded
    n n n
    def setup(self):
       x = self.x = Variable("x")
        return [x >= 1]
print("SCALAR")
m = Test()
m.cost = m["x"]
print (m.solve (verbosity=0).summary())
print("_____\n")
print("VECTORIZED")
with Vectorize(3):
   m = Test()
m.cost = m["x"].prod()
m.append(m["x"][1] >= 2)
print (m.solve (verbosity=0).summary())
```

```
SCALAR

Optimal Cost
------

1

Free Variables
-----
x : 1
```

## 6.5 Multipoint analysis modeling

In many engineering models, there is a physical object that is operated in multiple conditions. Some variables correspond to the design of the object (size, weight, construction) while others are vectorized over the different conditions (speed, temperature, altitude). By combining named models and vectorization we can create intuitive representations of these systems while maintaining modularity and interoperability.

In the example below, the models Aircraft and Wing have a .dynamic() method which creates instances of AircraftPerformance and WingAero, respectively. The Aircraft and Wing models create variables, such as size and weight without fuel, that represent a physical object. The dynamic models create properties that change based on the flight conditions, such as drag and fuel weight.

This means that when an aircraft is being optimized for a mission, you can create the aircraft (AC in this example) and then pass it to a Mission model which can create vectorized aircraft performance models for each flight segment and/or flight condition.

```
"""Modular aircraft concept"""
import pickle
import numpy as np
from gpkit import Model, Vectorize, parse_variables

class AircraftP(Model):
    """Aircraft flight physics: weight <= lift, fuel burn

    Variables

# CHAPTER 7

## **Advanced Commands**

# 7.1 Derived Variables

#### 7.1.1 Evaluated Fixed Variables

Some fixed variables may be derived from the values of other fixed variables. For example, air density, viscosity, and temperature are functions of altitude. These can be represented by a substitution or value that is a one-argument function accepting model.substitutions (for details, see *Substitutions* below).

```
"Example pre-solve evaluated fixed variable"
from gpkit import Variable, Model

# code from t_GPSubs.test_calcconst in tests/t_sub.py
x = Variable("x", "hours")
t_day = Variable("t_{{day}}", 12, "hours")
t_night = Variable("t_{{night}}", lambda c: 24 - c[t_day], "hours")

# note that t_night has a function as its value
m = Model(x, [x >= t_day, x >= t_night])
sol = m.solve(verbosity=0)
assert sol["variables"][t_night] == 12

# call substitutions
m.substitutions.update({t_day: ("sweep", [8, 12, 16])})
sol = m.solve(verbosity=0)
assert (sol["variables"][t_night] == [16, 12, 8]).all()
```

These functions are automatically differentiated with the ad package to provide more accurate sensitivities. In some cases may require using functions from the ad.admath instead of their python or numpy equivalents; the ad documentation contains details on how to do this.

### 7.1.2 Evaluated Free Variables

Some free variables may be evaluated from the values of other (non-evaluated) free variables after the optimization is performed. For example, if the efficiency  $\nu$  of a motor is not a GP-compatible variable, but  $(1-\nu)$  is a valid GP variable, then  $\nu$  can be calculated after solving. These evaluated free variables can be represented by a Variable with evalfn metadata. Note that this variable should not be used in constructing your model!

```
"Example post-solve evaluated variable"
from gpkit import Variable, Model

# code from t_constraints.test_evalfn in tests/t_sub.py
x = Variable("x")
x2 = Variable("x^2", evalfn=lambda v: v[x]**2)
m = Model(x, [x >= 2])
m.unique_varkeys = set([x2.key])
sol = m.solve(verbosity=0)
assert abs(sol(x2) - 4) <= 1e-4</pre>
```

For evaluated variables that can be used during a solution, see Sequential Geometric Programs.

# 7.2 Sweeps

Sweeps are useful for analyzing tradeoff surfaces. A sweep "value" is an Iterable of numbers, e.g. [1, 2, 3]. The simplest way to sweep a model is to call model.sweep({sweepvar: sweepvalues}), which will return a solution array but not change the model's substitutions dictionary. If multiple sweepvars are given, the method will run them all as independent one-dimensional sweeps and return a list of one solution per sweep. The method model.autosweep({sweepvar: (start, end)}, tol=0.01) behaves very similarly, except that only the bounds of the sweep need be specified and the region in betwen will be swept to a maximum possible error of tol in the log of the cost. For details see *ID Autosweeps* below.

## 7.2.1 Sweep Substitutions

Alternatively, or to sweep a higher-dimensional grid, Variables can swept with a substitution value takes the form ('sweep', Iterable), such as ('sweep', np.linspace(1e6, 1e7, 100)). During variable declaration, giving an Iterable value for a Variable is assumed to be giving it a sweep value: for example, x = Variable("x", [1, 2, 3]) will sweep x over three values.

Vector variables may also be substituted for:  $\{y: ("sweep", [[1, 2], [1, 2], [1, 2]) \}$  will sweep  $y \forall y_i \in \{1, 2\}$ . These sweeps cannot be specified during Variable creation.

A Model with sweep substitutions will solve for all possible combinations: e.g., if there's a variable x with value ('sweep', [1, 3]) and a variable y with value ('sweep', [14, 17]) then the gp will be solved four times, for  $(x,y) \in \{(1,14), (1,17), (3,14), (3,17)\}$ . The returned solutions will be a one-dimensional array (or 2-D for vector variables), accessed in the usual way.

## 7.2.2 1D Autosweeps

If you're only sweeping over a single variable, autosweeping lets you specify a tolerance for cost error instead of a number of exact positions to solve at. GPkit will then search the sweep segment for a locally optimal number of sweeps that can guarantee a max absolute error on the log of the cost.

Accessing variable and cost values from an autosweep is slightly different, as can be seen in this example:

```
"Show autosweep_1d functionality"
import pickle
import numpy as np
import gpkit
from gpkit import units, Variable, Model
from gpkit.tools.autosweep import autosweep_1d
from gpkit.small_scripts import mag
A = Variable("A", "m**2")
l = Variable("1", "m")
m1 = Model(A**2, [A >= 1**2 + units.m**2])
t.ol1 = 1e-3
bst1 = autosweep_1d(m1, tol1, 1, [1, 10], verbosity=0)
print("Solved after 2i passes, cost logtol +/-8.3g" % (bst1.nsols, bst1.
→tol))
# autosweep solution accessing
1_vals = np.linspace(1, 10, 10)
sol1 = bst1.sample_at(l_vals)
print("values of 1: %s" % 1_vals)
print("values of A: %s" % sol1("A"))
cost_estimate = sol1["cost"]
cost_lb, cost_ub = soll.cost_lb(), soll.cost_ub()
print("cost lower bound:\n%s\n" % cost_lb)
print("cost estimate:\n%s\n" % cost_estimate)
print("cost upper bound:\n^{s}\n^{"} % cost_ub)
# you can evaluate arbitrary posynomials
np.testing.assert_allclose(mag(2*sol1(A)), mag(sol1(<math>2*A)))
assert (sol1["cost"] == sol1(A**2)).all()
# the cost estimate is the logspace mean of its upper and lower bounds
np.testing.assert_allclose((np.log(mag(cost_lb)) + np.log(mag(cost_ub)))/2,
                           np.log(mag(cost_estimate)))
# save autosweep to a file and retrieve it
bst1.save("autosweep.pkl")
bst1_loaded = pickle.load(open("autosweep.pkl", "rb"))
# this problem is two intersecting lines in logspace
m2 = Model(A**2, [A >= (1/3)**2, A >= (1/3)**0.5 * units.m**1.5])
tol2 = {"mosek": 1e-12, "cvxopt": 1e-7,
        "mosek_cli": 1e-6,
        'mosek_conif': 1e-6}[gpkit.settings["default_solver"]]
# test Model method
sol2 = m2.autosweep(\{1: [1, 10]\}, tol2, verbosity=0)
bst2 = sol2.bst
print("Solved after %2i passes, cost logtol +/-\%.3g" % (bst2.nsols, bst2.
→t.ol))
print("Table of solutions used in the autosweep:")
print(bst2.solarray.table())
```

If you need access to the raw solutions arrays, the smallest simplex tree containing any given point can be gotten with min\_bst = bst.min\_bst(val), the extents of that tree with bst.bounds and solutions of that tree with bst.sols. More information is in help(bst).

7.2. Sweeps 39

# 7.3 Tight ConstraintSets

Tight ConstraintSets will warn if any inequalities they contain are not tight (that is, the right side does not equal the left side) after solving. This is useful when you know that a constraint *should* be tight for a given model, but representing it as an equality would be non-convex.

# 7.4 Loose ConstraintSets

Loose ConstraintSets will warn if any GP-compatible constraints they contain are not loose (that is, their sensitivity is above some threshold after solving). This is useful when you want a constraint to be inactive for a given model because it represents an important model assumption (such as a fit only valid over a particular interval).

# 7.5 Substitutions

Substitutions are a general-purpose way to change every instance of one variable into either a number or another variable.

# 7.5.1 Substituting into Posynomials, Nomial Arrays, and GPs

The examples below all use Posynomials and NomialArrays, but the syntax is identical for GPs (except when it comes to sweep variables).

```
"Example substitution; adapted from t_sub.py/t_NomialSubs /test_Basic"
from gpkit import Variable
x = Variable("x")
p = x**2
assert p.sub({x: 3}) == 9
```

```
assert p.sub({x.key: 3}) == 9
assert p.sub({"x": 3}) == 9
```

Here the variable x is being replaced with 3 in three ways: first by substituting for x directly, then by substituting for the VarKey("x"), then by substituting the string "x". In all cases the substitution is understood as being with the VarKey: when a variable is passed in the VarKey is pulled out of it, and when a string is passed in it is used as an argument to the Posynomial's Varkeys dictionary.

# 7.5.2 Substituting multiple values

```
"Example substitution; adapted from t_sub.py/t_NomialSubs/test_Vector"
from gpkit import Variable, VectorVariable
x = Variable("x")
y = Variable("y")
z = VectorVariable(2, "z")
p = x*y*z
assert all(p.sub({x: 1, "y": 2}) == 2*z)
assert all(p.sub({x: 1, y: 2, "z": [1, 2]}) == z.sub({z: [2, 4]}))
```

To substitute in multiple variables, pass them in as a dictionary where the keys are what will be replaced and values are what it will be replaced with. Note that you can also substitute for VectorVariables by their name or by their NomialArray.

# 7.5.3 Substituting with nonnumeric values

You can also substitute in sweep variables (see *Sweeps*), strings, and monomials:

Note that units are preserved, and that the value can be either a string (in which case it just renames the variable), a varkey (in which case it changes its description, including the name) or a Monomial (in which case it substitutes for the variable with a new monomial).

# 7.5.4 Updating ConstraintSet substitutions

ConstraintSets have a .substitutions KeyDict attribute which will be substituted before solving. This KeyDict accepts variable names, VarKeys, and Variable objects as keys, and can be updated (or deleted from) like a regular Python dictionary to change the substitutions that will be used at solve-time. If a ConstraintSet itself contains ConstraintSets, it and all its elements share pointers to the same substitutions dictionary object, so that updating any one of them will update all of them.

#### 7.5.5 Fixed Variables

When a Model is created, any fixed Variables are used to form a dictionary: {var: var.descr["value"] for var in self.varlocs if "value" in var.descr}. This dictionary in then substituted into the Model's cost and constraints before the substitutions argument is (and hence values are supplanted by any later substitutions).

solution.subinto(p) will substitute the solution(s) for variables into the posynomial p, returning a NomialArray. For a non-swept solution, this is equivalent to p.sub(solution["variables"]).

You can also substitute by just calling the solution, i.e. solution (p). This returns a numpy array of just the coefficients (c) of the posynomial after substitution, and will raise a 'ValueError' if some of the variables in p were not found in solution.

7.5. Substitutions 41

## 7.5.6 Freeing Fixed Variables

After creating a Model, it may be useful to "free" a fixed variable and resolve. This can be done using the command del m.substitutions["x"], where m is a Model. An example of how to do this is shown below.

```
"Example of freeing fixed variables"
from gpkit import Variable, Model
x = Variable("x")
y = Variable("y", 3)  # fix value to 3
m = Model(x, [x >= 1 + y, y >= 1])
sol = m.solve()  # optimal cost is 4; y appears in sol["constants"]

assert abs(sol["cost"] - 4) <= 1e-4
assert y in sol["constants"]

del m.substitutions["y"]
sol = m.solve()  # optimal cost is 2; y appears in Free Variables
assert abs(sol["cost"] - 2) <= 1e-4
assert y in sol["freevariables"]</pre>
```

Note that del m.substitutions["y"] affects m but not y.key. y.value will still be 3, and if y is used in a new model, it will still carry the value of 3.

# CHAPTER 8

# Signomial Programming

Signomial programming finds a local solution to a problem of the form:

```
\begin{array}{ll} \text{minimize} & g_0(x) \\ \text{subject to} & f_i(x)=1, & i=1,....,m \\ & g_i(x)-h_i(x)\leq 1, & i=1,....,n \end{array}
```

where each f is monomial while each g and h is a posynomial.

This requires multiple solutions of geometric programs, and so will take longer to solve than an equivalent geometric programming formulation.

In general, when given the choice of which variables to include in the positive-posynomial / g side of the constraint, the modeler should:

- 1. maximize the number of variables in g,
- 2. prioritize variables that are in the objective,
- 3. then prioritize variables that are present in other constraints.

The .localsolve syntax was chosen to emphasize that signomial programming returns a local optimum. For the same reason, calling .solve on an SP will raise an error.

By default, signomial programs are first solved conservatively (by assuming each h is equal only to its constant portion) and then become less conservative on each iteration.

# 8.1 Example Usage

```
"""Adapted from t_SP in tests/t_geometric_program.py"""
from gpkit import Model, Variable, SignomialsEnabled

# Decision variables
x = Variable('x')
y = Variable('y')
```

When using the localsolve method, the reltol argument specifies the relative tolerance of the solver: that is, by what percent does the solution have to improve between iterations? If any iteration improves less than that amount, the solver stops and returns its value.

If you wish to start the local optimization at a particular point  $x_k$ , however, you may do so by putting that position (a dictionary formatted as you would a substitution) as the xk argument.

# 8.2 Sequential Geometric Programs

The method of solving local GP approximations of a non-GP compatible model can be generalized, at the cost of the general smoothness and lack of a need for trust regions that SPs guarantee.

For some applications, it is useful to call external codes which may not be GP compatible. Imagine we wished to solve the following optimization problem:

```
\begin{array}{ll} \text{minimize} & y \\ \text{subject to} & y \geq \sin(x) \\ & \frac{\pi}{4} \leq x \leq \frac{\pi}{2} \end{array}
```

This problem is not GP compatible due to the sin(x) constraint. One approach might be to take the first term of the Taylor expansion of sin(x) and attempt to solve:

Assume we have some external code which is capable of evaluating our incompatible function:

```
"""External function for GPkit to call. Can be found
in gpkit/docs/source/examples/external_function.py"""
import numpy as np

def external_code(x):
    "Returns sin(x)"
    return np.sin(x)
```

Now, we can create a ConstraintSet that allows GPkit to treat the incompatible constraint as though it were a signomial programming constraint:

```
"Can be found in gpkit/docs/source/examples/external_constraint.py"
from external_function import external_code
class ExternalConstraint:
    "Class for external calling"
    def __init__(self, x, y):
        # We need a GPkit variable defined to return in our constraint. The
        # easiest way to do this is to read in the parameters of interest in
        # the initiation of the class and store them here.
        self.x = x
        self.y = y
    def as_gpconstr(self, x0):
        "Returns locally-approximating GP constraint"
        # Creating a default constraint for the first solve
        if self.x not in x0:
            return (self.y >= self.x)
        # Otherwise calls external code at the current position...
        x_star = x0[self.x]
        res = external_code(x_star)
        # ...and returns a linearized posy <= 1
        return (self.y >= res * self.x/x_star)
```

and replace the incompatible constraint in our GP:

which is the expected result. This method has been generalized to larger problems, such as calling XFOIL and AVL.

If you wish to start the local optimization at a particular point  $x_0$ , however, you may do so by putting that position (a dictionary formatted as you would a substitution) as the  $\times 0$  argument

# CHAPTER 9

Examples

# 9.1 iPython Notebook Examples

More examples, including some with in-depth explanations and interactive visualizations, can be seen on nbviewer.

# 9.2 A Trivial GP

The most trivial GP we can think of: minimize x subject to the constraint  $x \ge 1$ .

```
"Very simple problem: minimize x while keeping x greater than 1."
from gpkit import Variable, Model

# Decision variable
x = Variable("x")

# Constraint
constraints = [x >= 1]

# Objective (to minimize)
objective = x

# Formulate the Model
m = Model(objective, constraints)

# Solve the Model
sol = m.solve(verbosity=0)

# print selected results
print("Optimal cost: %.4g" % sol["cost"])
print("Optimal x val: %.4g" % sol["variables"][x])
```

Of course, the optimal value is 1. Output:

```
Optimal cost: 1
Optimal x val: 1
```

# 9.3 Maximizing the Volume of a Box

This example comes from Section 2.4 of the GP tutorial, by S. Boyd et. al.

```
"Maximizes box volume given area and aspect ratio constraints."
from gpkit import Variable, Model
# Parameters
alpha = Variable("alpha", 2, "-", "lower limit, wall aspect ratio")
beta = Variable("beta", 10, "-", "upper limit, wall aspect ratio")
gamma = Variable("gamma", 2, "-", "lower limit, floor aspect ratio")
delta = Variable("delta", 10, "-", "upper limit, floor aspect ratio")
A_wall = Variable("A_{wall}", 200, "m^2", "upper limit, wall area")
A_floor = Variable("A_{floor}", 50, "m^2", "upper limit, floor area")
# Decision variables
h = Variable("h", "m", "height")
w = Variable("w", "m", "width")
d = Variable("d", "m", "depth")
# Constraints
constraints = [A_wall >= 2*h*w + 2*h*d,
                A_floor >= w*d
                h/w >= alpha,
                h/w <= beta,
                d/w >= gamma,
                d/w <= delta]</pre>
# Objective function
objective = 1/V # To maximize V, we minimize its reciprocal
# Formulate the Model
m = Model(objective, constraints)
# Solve the Model and print the results table
print (m.solve (verbosity=0).table())
```

#### The output is

```
Optimal Cost
------
0.003674

Free Variables
------
d: 8.17 [m] depth
h: 8.163 [m] height
w: 4.081 [m] width

# 9.6 Simple Beam

In this example we consider a beam subjected to a uniformly distributed transverse force along its length. The beam has fixed geometry so we are not optimizing its shape, rather we are simply solving a discretization of the Euler-Bernoulli beam bending equations using GP.

# CHAPTER 10

Glossary

For an alphabetical listing of all commands, check out the genindex

# 10.1 gpkit package

# 10.1.1 Subpackages

### gpkit.constraints package

#### **Submodules**

#### gpkit.constraints.array module

### Implements ArrayConstraint

A ConstraintSet for prettier array-constraint printing.

ArrayConstraint gets its *sub* method from ConstrainSet, and so *left* and *right* are only used for printing.

When created by NomialArray *left* and *right* are likely to be either NomialArrays or Varkeys of VectorVariables.

### lines\_without (excluded)

Returns lines for indentation in hierarchical printing.

#### gpkit.constraints.bounded module

```
Implements Bounded
class gpkit.constraints.bounded.Bounded(constraints, *, verbosity=1, eps=1e-
                                                      30, lower=None, upper=None)
     Bases: gpkit.constraints.set.ConstraintSet
     Bounds contained variables so as to ensure dual feasibility.
     constraints [iterable] constraints whose varkeys will be bounded
     verbosity [int (default 1)]
          how detailed of a warning to print 0: nothing 1: print warnings
     eps [float (default 1e-30)] default lower bound is eps, upper bound is 1/eps
     lower [float (default None)] lower bound for all varkeys, replaces eps
     upper [float (default None)] upper bound for all varkeys, replaces 1/eps
     check_boundaries (result, *, verbosity=0)
          Creates (and potentially prints) a dictionary of unbounded variables.
     logtol_threshold = 3
     process result (result)
          Add boundedness to the model's solution
     sens_threshold = 1e-07
gpkit.constraints.bounded.varkey_bounds(varkeys, lower, upper)
     Returns constraints list bounding all varkeys.
     varkeys [iterable] list of varkeys to create bounds for
     lower [float] lower bound for all varkeys
     upper [float] upper bound for all varkeys
gpkit.constraints.costed module
Implement CostedConstraintSet
class gpkit.constraints.costed.CostedConstraintSet (cost, constraints, sub-
                                                                    stitutions=None)
     Bases: gpkit.constraints.set.ConstraintSet
     A ConstraintSet with a cost
     cost: gpkit.Posynomial constraints: Iterable substitutions: dict (None)
     constrained_varkeys()
          Return all varkeys in the cost and non-ConstraintSet constraints
     lineage = None
```

#### gpkit.constraints.gp module

Implement the GeometricProgram class

```
class gpkit.constraints.gp.GeometricProgram (cost, constraints, substitutions,
                                                            *. checkbounds=True)
     Bases: object
     Standard mathematical representation of a GP.
     solver_out and solve_log are set during a solve result is set at the end of a solve if solution status is
     optimal
     >>> gp = gpkit.geometric_program.GeometricProgram(
                              # minimize
                              Х,
                                   # subject to
                                   1/x # <= 1, implicitly
                              ], {})
      >>> gp.solve()
     check_bounds (*, err_on_missing_bounds=False)
          Checks if any variables are unbounded, through equality constraints.
     check solution (cost, primal, nu, la, tol, abstol=1e-20)
          Run checks to mathematically confirm solution solves this GP
          cost: float cost returned by solver
          primal: list primal solution returned by solver
          nu: numpy.ndarray monomial lagrange multiplier
          la: numpy.ndarray posynomial lagrange multiplier
          Infeasible if any problems are found
     gen()
          Generates nomial and solve data (A, p_idxs) from posynomials
     generate_result (solver_out, *, verbosity=0, dual_check=True)
          Generates a full SolutionArray and checks it.
     model = None
     nu by posy = None
     result
          Creates and caches a result from the raw solver_out
     solve (solver=None, *, verbosity=1, gen_result=True, **kwargs)
          Solves a GeometricProgram and returns the solution.
          solver [str or function (optional)] By default uses a solver found during installation. If
               "mosek_conif", "mosek_cli", or "cvxopt", uses that solver. If a function, passes that
               function cs, A, p_idxs, and k.
          verbosity [int (default 1)] If greater than 0, prints solver name and solve time.
          **kwargs: Passed to solver constructor and solver function.
          result : SolutionArray
     solve_log = None
     solver_out = None
     v ss = None
```

```
class gpkit.constraints.gp.MonoEqualityIndexes
     Bases: object
     Class to hold MonoEqualityIndexes
gpkit.constraints.gp.fulfill_meq_bounds (missingbounds, meq_bounds)
     Bounds variables with monomial equalities
gpkit.constraints.gp.gen_meq_bounds (missingbounds, exps, meq_idxs)
     Generate conditional monomial equality bounds
gpkit.constraints.loose module
Implements Loose
class gpkit.constraints.loose.Loose(constraints, *, senstol=None)
     Bases: gpkit.constraints.set.ConstraintSet
     ConstraintSet whose inequalities must result in an equality.
     process_result (result)
          Checks that all constraints are satisfied with equality
     raiseerror = False
     senstol = 1e-05
gpkit.constraints.model module
Implements Model
class gpkit.constraints.model.Model(cost=None,
                                                              constraints=None,
                                                                                   *args.
                                                 **kwargs)
     Bases: gpkit.constraints.costed.CostedConstraintSet
     Symbolic representation of an optimization problem.
     The Model class is used both directly to create models with constants and sweeps, and indirectly
     inherited to create custom model classes.
     cost [Posynomial (optional)] Defaults to Monomial(1).
     constraints [ConstraintSet or list of constraints (optional)] Defaults to an empty list.
     substitutions [dict (optional)] This dictionary will be substituted into the problem before solving,
          and also allows the declaration of sweeps and linked sweeps.
     program is set during a solve solution is set at the end of a solve
     autosweep (sweeps, tol=0.01, samplepoints=100, **solveargs)
          Autosweeps {var: (start, end)} pairs in sweeps to tol.
          Returns swept and sampled solutions. The original simplex tree can be accessed at sol.bst
     debug (solver=None, verbosity=1, **solveargs)
          Attempts to diagnose infeasible models.
     gp (constants=None, **initargs)
          Return program version of self
     localsolve (solver=None, *, verbosity=1, skipsweepfailures=False, **solveargs)
          Forms a mathematical program and attempts to solve it.
```

```
solver [string or function (default None)] If None, uses the default solver found in installation.
verbosity [int (default 1)] If greater than 0 prints runtime messages. Is decremented by one and then passed to programs.
skipsweepfailures [bool (default False)] If True, when a solve errors during a sweep, skip it.
**solveargs: Passed to solve() call
sol [SolutionArray] See the SolutionArray documentation for details.
ValueError if the program is invalid. RuntimeWarning if an error occurs in solving or parsing the solution.
```

```
program = None
solution = None
solve(solver=None, *, verbosity=1, skipsweepfailures=False, **solveargs)
Forms a mathematical program and attempts to solve it.
```

**solver** [string or function (default None)] If None, uses the default solver found in installation.

**verbosity** [int (default 1)] If greater than 0 prints runtime messages. Is decremented by one and then passed to programs.

skipsweepfailures [bool (default False)] If True, when a solve errors during a sweep, skip it.

\*\*solveargs : Passed to solve() call

sol [SolutionArray] See the SolutionArray documentation for details.

ValueError if the program is invalid. RuntimeWarning if an error occurs in solving or parsing the solution.

```
sp (constants=None, **initargs)
    Return program version of self

sweep (sweeps, **solveargs)
    Sweeps {var: values} pairs in sweeps. Returns swept solutions.

verify_docstring()
    Verifies docstring bounds are sufficient but not excessive.

gpkit.constraints.model.get_relaxed(relaxvals, mapped_list, min_return=1)
    Determines which relaxvars are considered 'relaxed'
```

#### gpkit.constraints.prog\_factories module

```
Scripts for generating, solving and sweeping programs
```

program: NomialData Class to return, e.g. GeometricProgram or SequentialGeometricProgram

return\_attr: string attribute to return in addition to the program

Generates function that returns a program() and optionally an attribute.

gpkit.constraints.prog\_factories.solvify(genfunction)
 Returns function for making/solving/sweeping a program.

### gpkit.constraints.relax module

Models for assessing primal feasibility

Bases: gpkit.constraints.set.ConstraintSet

Relax constants in a constraintset.

constraints [iterable] Constraints which will be relaxed (made easier).

include\_only [set (optional)] variable names must be in this set to be relaxed

exclude [set (optional)] variable names in this set will never be relaxed

**relaxvars** [Variable] The variables controlling the relaxation. A solved value of 1 means no relaxation was necessary or optimal for a particular constant. Higher values indicate the amount by which that constant has been made easier: e.g., a value of 1.5 means it was made 50 percent easier in the final solution than in the original problem. Of course, this can also be determined by looking at the constant's new value directly.

```
process_result (result)
```

Transfers the constant sensitivities back to the original constants

```
class gpkit.constraints.relax.ConstraintsRelaxed(original_constraints)
```

Bases: gpkit.constraints.set.ConstraintSet

Relax constraints, as in Eqn. 11 of [Boyd2007].

**constraints** [iterable] Constraints which will be relaxed (made easier).

**relaxvars** [Variable] The variables controlling the relaxation. A solved value of 1 means no relaxation was necessary or optimal for a particular constraint. Higher values indicate the amount by which that constraint has been made easier: e.g., a value of 1.5 means it was made 50 percent easier in the final solution than in the original problem.

[Boyd2007]: "A tutorial on geometric programming", Optim Eng 8:67-122

Relax constraints the same amount, as in Eqn. 10 of [Boyd2007].

constraints [iterable] Constraints which will be relaxed (made easier).

**relaxvar** [Variable] The variable controlling the relaxation. A solved value of 1 means no relaxation. Higher values indicate the amount by which all constraints have been made easier: e.g.,

a value of 1.5 means all constraints were 50 percent easier in the final solution than in the original problem.

[Boyd2007]: "A tutorial on geometric programming", Optim Eng 8:67-122

### gpkit.constraints.set module

```
Implements ConstraintSet
class gpkit.constraints.set.ConstraintSet(constraints, substitutions=None)
     Bases: list, gpkit.repr_conventions.ReprMixin
     Recursive container for ConstraintSets and Inequalities
     as_hmapslt1 (subs)
          Yields hmaps<=1 from self.flat()
     as_view()
          Return a ConstraintSetView of this ConstraintSet.
     constrained_varkeys()
          Return all varkeys in non-ConstraintSet constraints
     flat (yield if hasattr=None)
          Yields contained constraints, optionally including constraintsets.
     idxlookup = {}
     latex (excluded=('units', ))
          LaTeX representation of a ConstraintSet.
     lines_without (excluded)
          Lines representation of a ConstraintSet.
     name_collision_varkeys()
          Returns the set of contained varkeys whose names are not unique
     process_result (result)
          Does arbitrary computation / manipulation of a program's result
          There's no guarantee what order different constraints will process results in, so any changes
          made to the program's result should be careful not to step on other constraint's toes.
            · check that an inequality was tight
            · add values computed from solved variables
     str_without (excluded=('unnecessary lineage', 'units'))
          String representation of a ConstraintSet.
     unique_varkeys = frozenset()
     variables_byname (key)
          Get all variables with a given name
class gpkit.constraints.set.ConstraintSetView(constraintset, index=())
     Bases: object
     Class to access particular views on a set's variables
gpkit.constraints.set.add_meq_bounds(bounded, meq_bounded)
     Iterates through meq_bounds until convergence
```

10.1. gpkit package

```
gpkit.constraints.set.badelement (cns, i, constraint, cause=")
    Identify the bad element and raise a ValueError

gpkit.constraints.set.flatiter(iterable, yield_if_hasattr=None)
    Yields contained constraints, optionally including constraintsets.

gpkit.constraints.set.recursively_line(iterable, excluded)
    Generates lines in a recursive tree-like fashion, the better to indent.

gpkit.constraints.set.sort_constraints_dict(iterable)
    Sort a dictionary of {k: constraint} and return its keys and values
```

#### gpkit.constraints.sgp module

Implement the SequentialGeometricProgram class

Bases: object

Prepares a collection of signomials for a SP solve.

cost [Posynomial] Objective to minimize when solving

**constraints** [list of Constraint or SignomialConstraint objects] Constraints to maintain when solving (implicitly Signomials <= 1)

**verbosity** [int (optional)] Currently has no effect: SequentialGeometricPrograms don't know anything new after being created, unlike GeometricPrograms.

gps is set during a solve result is set at the end of a solve

```
gp (x0=None, *, cleanx0=False)
Update self._gp for x0 and return it.
```

```
gps = None
```

```
localsolve (solver=None, *, verbosity=1, x0=None, reltol=0.0001, iteration_limit=50, **solveargs)
```

Locally solves a SequentialGeometricProgram and returns the solution.

**solver** [str or function (optional)] By default uses one of the solvers found during installation. If set to "mosek", "mosek\_cli", or "cvxopt", uses that solver. If set to a function, passes that function cs, A, p\_idxs, and k.

**verbosity** [int (optional)] If greater than 0, prints solve time and number of iterations. Each GP is created and solved with verbosity one less than this, so if greater than 1, prints solver name and time for each GP.

```
x0 [dict (optional)] Initial location to approximate signomials about.
reltol [float] Iteration ends when this is greater than the distance between two consecutive solve's objective values.
iteration_limit [int] Maximum GP iterations allowed.
```

**mutategp: boolean** Prescribes whether to mutate the previously generated GP or to create a new GP with every solve.

\*\*solveargs: Passed to solver function.

result [dict] A dictionary containing the translated solver result.

```
model = None
result = None
results
    Creates and caches results from the raw solver_outs
slack = gpkit.Variable(SGP.PCCPslack)
solver_outs = None
```

#### gpkit.constraints.sigeq module

Implements SignomialEquality

A constraint of the general form posynomial == posynomial

#### gpkit.constraints.single\_equation module

```
Implements SingleEquationConstraint
```

#### gpkit.constraints.tight module

```
Implements Tight
class gpkit.constraints.tight.Tight (constraints, *, reltol=None, **kwargs)
    Bases: gpkit.constraints.set.ConstraintSet
    ConstraintSet whose inequalities must result in an equality.
    process_result (result)
        Checks that all constraints are satisfied with equality
    reltol = 0.001
```

#### **Module contents**

Contains ConstraintSet and related classes and objects

### gpkit.interactive package

#### **Submodules**

### gpkit.interactive.plot\_sweep module

```
Implements plot_sweep1d function
```

```
gpkit.interactive.plot_sweep.assign_axes (var, posys, axes)
    Assigns axes to posys, creating and formatting if necessary

gpkit.interactive.plot_sweep.format_and_label_axes (var, posys, axes, ylabel=True)
    Formats and labels axes

gpkit.interactive.plot_sweep.plot_ldsweepgrid (model, sweeps, posys, origsol=None, tol=0.01, **solveargs)

Creates and plots a sweep from an existing model

Example usage: f, _ = plot_sweep_ld(m, {'x': np.linspace(1, 2, 5)}, 'y') f.savefig('mysweep.png')
```

### gpkit.interactive.plotting module

```
Plotting methods
```

model: Model Signomial programming model that has already been solved

matplotlib.pyplot Figure Plot of cost as functions of SP iteration #

#### gpkit.interactive.sankey module

#### gpkit.interactive.widgets module

#### Module contents

Module for the interactive and plotting functions of GPkit

#### gpkit.nomials package

#### **Submodules**

#### gpkit.nomials.array module

Module for creating NomialArray instances.

#### **Example**

```
>>> x = gpkit.Monomial('x')
>>> px = qpkit.NomialArray([1, x, x**2])
class gpkit.nomials.array.NomialArray
     Bases: gpkit.repr_conventions.ReprMixin, numpy.ndarray
     A Numpy array with elementwise inequalities and substitutions.
     input array: array-like
     >>> px = gpkit.NomialArray([1, x, x**2])
     latex (excluded=())
          Returns latex representation without certain fields.
     outer(other)
          Returns the array and argument's outer product.
     prod (*args, **kwargs)
          Returns a product. O(N) if no arguments and only contains monomials.
     str_without (excluded=())
          Returns string without certain fields (such as 'lineage').
     sub (subs, require_positive=True)
          Substitutes into the array
     sum(*args, **kwargs)
          Returns a sum. O(N) if no arguments are given.
     vectorize(function, *args, **kwargs)
          Apply a function to each terminal constraint, returning the array
```

```
gpkit.nomials.array.array_constraint (symbol, func)
    Return function which creates constraints of the given operator.
```

#### gpkit.nomials.core module

```
The shared non-mathematical backbone of all Nomials

class gpkit.nomials.core.Nomial (hmap)

Bases: gpkit.nomials.data.NomialData

Shared non-mathematical properties of all nomials

latex (excluded=())

Latex representation, parsing excluded just as .str_without does

prod()

Return self for compatibility with NomialArray

str_without (excluded=())

String representation, excluding fields ('units', varkey attributes)

sub = None

sum()

Return self for compatibility with NomialArray
```

Self, with values substituted for variables that have values

float, if no symbolic variables remain after substitution (Monomial, Posynomial, or Nomial), otherwise.

```
gpkit.nomials.core.nomial_latex_helper(c, pos_vars, neg_vars)
```

Combines (varlatex, exponent) tuples, separated by positive vs negative exponent, into a single latex string.

#### gpkit.nomials.data module

Machinery for exps, cs, varlocs data – common to nomials and programs

```
class gpkit.nomials.data.NomialData(hmap)
    Bases: gpkit.repr_conventions.ReprMixin
```

Object for holding cs, exps, and other basic 'nomial' properties.

cs: array (coefficient of each monomial term) exps: tuple of {VarKey: float} (exponents of each monomial term) varlocs: {VarKey: list} (terms each variable appears in) units: pint.UnitsContainer

cs

Create cs or return cached cs

exps

Create exps or return cached exps

to (units)

Create new Signomial converted to new units

varkeys

The NomialData's varkeys, created when necessary for a substitution.

#### gpkit.nomials.map module

```
Implements the NomialMap class
class gpkit.nomials.map.NomialMap
      Bases: gpkit.small_classes.HashVector
     Class for efficent algebraic represention of a nomial
     A NomialMap is a mapping between hashvectors representing exponents and their coefficients in a
     posynomial.
     For example, \{\{x:1\}: 2.0, \{y:1\}: 3.0\} represents 2^*x + 3^*y, where x and y are VarKey objects.
      copy()
           Return a copy of this
     csmap = None
     diff(varkey)
           Differentiates a NomialMap with respect to a varkey
     expmap = None
     mmap (orig)
           Maps substituted monomials back to the original nomial
           self.expmap is the map from pre- to post-substitution exponents, and takes the
                                                                                              form
               {original_exp: new_exp}
           self.csmap is the map from pre-substitution exponents to coefficients.
           m_from_ms is of the form {new_exp: [old_exps, ]}
           pmap is of the form [{orig_idx1: fraction1, orig_idx2: fraction2, },] where at the index
               corresponding to each new_exp is a dictionary mapping the indices corresponding to
               the old exps to their fraction of the post-substitution coefficient
      sub (substitutions, varkeys, parsedsubs=False)
           Applies substitutions to a NomialMap
           substitutions [(dict-like)] list of substitutions to perform
           varkeys [(set-like)] varkeys that are present in self (required argument so as to require effi-
               cient code)
           parsedsubs [bool] flag if the substitutions have already been parsed to contain only keys in
               varkeys
     to (to_units)
           Returns a new NomialMap of the given units
     units = None
     units_of_product (thing, thing2=None)
           Sets units to those of thing*thing2. Ugly optimized code.
gpkit.nomials.map.subinplace(cp, exp, o_exp, vk, cval, squished)
     Modifies cp by substituing cval/expval for vk in exp
```

#### gpkit.nomials.math module

Signomial, Posynomial, Monomial, Constraint, & MonoEQCOnstraint classes

```
class gpkit.nomials.math.Monomial (hmap=None, cs=1, require_positive=True)
     Bases: gpkit.nomials.math.Posynomial
     A Posynomial with only one term
          Creates c or returns a cached c
     exp
          Creates exp or returns a cached exp
     mono_approximation(x0)
          Monomial approximation about a point x0
          x0 (dict): point to monomialize about
          Monomial (unless self(x0) < 0, in which case a Signomial is returned)
class gpkit.nomials.math.MonomialEquality(left, right)
     Bases: gpkit.nomials.math.PosynomialInequality
     A Constraint of the form Monomial == Monomial.
     as_hmapslt1 (substitutions)
          Tags posynomials for dual feasibility checking
     oper = '='
     sens from dual (la, nu, )
          Returns the variable/constraint sensitivities from lambda/nu
class gpkit.nomials.math.Posynomial(hmap=None, cs=1, require_positive=True)
     Bases: gpkit.nomials.math.Signomial
     A Signomial with strictly positive cs
     mono_lower_bound(x0)
          Monomial lower bound at a point x0
          x0 (dict): point to make lower bound exact
          Monomial
class qpkit.nomials.math.PosynomialInequality(left, oper, right)
     Bases: gpkit.nomials.math.ScalarSingleEquationConstraint
     A constraint of the general form monomial >= posynomial Stored in the posylt1_rep attribute as a
     single Posynomial (self \leq 1) Usually initialized via operator overloading, e.g. cc = (y**2 >= 1 +
     x)
     as_hmapslt1 (substitutions)
          Returns the posys <= 1 representation of this constraint.
     feastol = 0.001
     sens_from_dual(la, nu, _)
          Returns the variable/constraint sensitivities from lambda/nu
class qpkit.nomials.math.ScalarSingleEquationConstraint (left,
                                                                                oper,
                                                                        right)
     Bases: gpkit.constraints.single_equation.SingleEquationConstraint
     A SingleEquationConstraint with scalar left and right sides.
     bounded = {}
     generated_by = None
```

```
meq_bounded = {}
     parent = None
     relaxed(relaxvar)
          Returns the relaxation of the constraint in a list.
     v ss = None
class gpkit.nomials.math.Signomial (hmap=None, cs=1, require_positive=True)
     Bases: gpkit.nomials.core.Nomial
     A representation of a Signomial.
     exps: tuple of dicts Exponent dicts for each monomial term
     cs: tuple Coefficient values for each monomial term
     require_positive: bool If True and Signomials not enabled, c <= 0 will raise ValueError
     Signomial Posynomial (if the input has only positive cs) Monomial (if the input has one term and
     only positive cs)
     chop()
          Returns a list of monomials in the signomial.
     diff(var)
          Derivative of this with respect to a Variable
          var [Variable key] Variable to take derivative with respect to
          Signomial (or Posynomial or Monomial)
     mono_approximation(x0)
          Monomial approximation about a point x0
          x0 (dict): point to monomialize about
          Monomial (unless self(x0) < 0, in which case a Signomial is returned)
     posy_negy()
          Get the positive and negative parts, both as Posynomials
          Posynomial: p_pos and p_neg in (self = p_pos - p_neg) decomposition,
     sub (substitutions, require positive=True)
          Returns a nomial with substitued values.
           3 == (x**2 + y).sub({(x': 1, y: 2)}) == (x).gp.sub(x, 3)
          substitutions [dict or key] Either a dictionary whose keys are strings, Variables, or VarKeys,
               and whose values are numbers, or a string, Variable or Varkey.
          val [number (optional)] If the substitutions entry is a single key, val holds the value
          require_positive [boolean (optional, default is True)] Controls whether the returned value
               can be a Signomial.
          Returns substituted nomial.
class qpkit.nomials.math.SignomialInequality (left, oper, right)
     Bases: gpkit.nomials.math.ScalarSingleEquationConstraint
     A constraint of the general form posynomial >= posynomial
     Stored at .unsubbed[0] as a single Signomial (0 \ge self)
```

10.1. gpkit package

```
as\_gpconstr(x0)
          Returns GP-compatible approximation at x0
     as_hmapslt1 (substitutions)
           Returns the posys <= 1 representation of this constraint.
     sens from dual (la, nu, result)
           We want to do the following chain: dlog(Obj)/dlog(monomial[i])
                                                                                      nu[i]
               dlog(monomial)/d(monomial) = 1/(monomial value) * d(monomial)/d(var) = see
               below * d(var)/dlog(var) = var = dlog(Obj)/dlog(var)
          each final monomial is really (coeff signomial)/(negy signomial)
          and by the chain rule d(monomial)/d(var) = d(coeff)/d(var)*1/negy
               d(1/\text{negy})/d(\text{var})*\text{coeff} = d(\text{coeff})/d(\text{var})*1/\text{negy} - d(\text{negy})/d(\text{var})*\text{coeff}*1/\text{negy}**2
class gpkit.nomials.math.SingleSignomialEquality(left, right)
     Bases: gpkit.nomials.math.SignomialInequality
     A constraint of the general form posynomial == posynomial
     as_gpconstr(x0)
          Returns GP-compatible approximation at x0
     as_hmapslt1 (substitutions)
          SignomialEquality is never considered GP-compatible
gpkit.nomials.substitution module
Scripts to parse and collate substitutions
qpkit.nomials.substitution.append_sub(sub, keys, constants, sweep, linkedsweep)
     Appends sub to constants, sweep, or linkedsweep.
qpkit.nomials.substitution.parse_subs (varkeys, substitutions, clean=False)
     Seperates subs into the constants, sweeps, linkedsweeps actually present.
gpkit.nomials.variables module
Implement Variable and Array Variable classes
class gpkit.nomials.variables.ArrayVariable
     Bases: gpkit.nomials.array.NomialArray
     A described vector of singlet Monomials.
     shape [int or tuple] length or shape of resulting array
     *args:
          may contain "name" (Strings)
                   "value" (Iterable) "units" (Strings)
               and/or "label" (Strings)
     **descr: VarKey description
     NomialArray of Monomials, each containing a VarKey with name '$name_{i}', where $name is
```

the vector's name and i is the VarKey's index.

```
class gpkit.nomials.variables.Variable(*args, **descr)
     Bases: gpkit.nomials.math.Monomial
     A described singlet Monomial.
     *args [list]
          may contain "name" (Strings)
                 "value" (Numbers + Quantity) or (Iterable) for a sweep "units" (Strings)
              and/or "label" (Strings)
     **descr [dict] VarKey description
     Monomials containing a VarKey with the name '$name', where $name is the vector's name and i is
     the VarKey's index.
     sub (*args, **kwargs)
          Same as nomial substitution, but also allows single-argument calls
          x = Variable('x') assert x.sub(3) == Variable('x', value=3)
     to (units)
          Create new Signomial converted to new units
class gpkit.nomials.variables.VectorizableVariable(*args, **descr)
     Bases:
              gpkit.nomials.variables.Variable, gpkit.nomials.variables.
     ArrayVariable
     A Variable outside a vectorized environment, an Array Variable within.
gpkit.nomials.variables.addmodelstodescr(descr, addtonamedvars=None)
     Add models to descr, optionally adding the second argument to NAMEDVARS
gpkit.nomials.variables.veclinkedfn(linkedfn, i)
     Generate an indexed linking function.
Module contents
Contains nomials, inequalities, and arrays
gpkit.solvers package
Submodules
gpkit.solvers.cvxopt module
gpkit.solvers.mosek cli module
Module for using the MOSEK EXPOPT command line interface
Example
result = _mosek.cli_expopt.imize(cs, A, p_idxs, "gpkit_mosek")
gpkit.solvers.mosek_cli.assert_equal(received, expected)
     Asserts that a file's next line is as expected.
```

10.1. gpkit package

```
qpkit.solvers.mosek_cli.optimize_generator(path=None, **_)
     Constructor for the MOSEK CLI solver function.
     path [str (optional)] The directory in which to put the MOSEK CLI input/output files. By default
          uses a system-appropriate temp directory.
gpkit.solvers.mosek_cli.read_vals(fil)
     Read numeric values until a blank line occurs.
gpkit.solvers.mosek_cli.remove_read_only(func, path, exc)
     If we can't remove a file/directory, change permissions and try again.
gpkit.solvers.mosek\_cli.write\_output\_file (filename, c, A, p_idxs)
     Writes a mosekexpopt compatible GP description to filename.
gpkit.solvers.mosek_conif module
Module contents
gpkit.tools package
Submodules
gpkit.tools.autosweep module
Tools for optimal fits to GP sweeps
class gpkit.tools.autosweep.BinarySweepTree (bounds, sols, sweptvar, cost-
     Bases: object
     Spans a line segment. May contain two subtrees that divide the segment.
     bounds [two-element list] The left and right boundaries of the segment
     sols [two-element list] The left and right solutions of the segment
     costs [array] The left and right logcosts of the segment
     splits [None or two-element list] If not None, contains the left and right subtrees
     splitval [None or float] The worst-error point, where the split will be if tolerance is too low
     splitlb [None or float] The cost lower bound at splitval
     splitub [None or float] The cost upper bound at splitval
     add_split (splitval, splitsol)
          Creates subtrees from bounds[0] to splitval and splitval to bounds[1]
     add_splitcost (splitval, splitlb, splitub)
          Adds a splitval, lower bound, and upper bound
     cost_at (_, value, bound=None)
          Logspace interpolates between split and costs. Guaranteed bounded.
     min bst (value)
          Returns smallest bst around value.
```

```
posy_at (posy, value)
          Logspace interpolates between sols to get posynomial values.
          No guarantees, just like a regular sweep.
     sample_at (values)
          Creates a SolutionOracle at a given range of values
     save (filename='autosweep.p')
          Pickles the autosweep and saves it to a file.
          The saved autosweep is identical except for two things:
                • the cost is made unitless
                • each solution's 'program' attribute is removed
          Solution can then be loaded with e.g.:
               >>> import cPickle as pickle
              >>> pickle.load(open("autosweep.p"))
     solarray
          Returns a solution array of all the solutions in an autosweep
     sollist
          Returns a list of all the solutions in an autosweep
class gpkit.tools.autosweep.SolutionOracle(bst, sampled_at)
     Bases: object
     Acts like a SolutionArray for autosweeps
     cost lb()
          Gets cost lower bounds from the BST and units them
     cost ub()
          Gets cost upper bounds from the BST and units them
     plot (posys=None, axes=None)
          Plots the sweep for each posy
qpkit.tools.autosweep.autosweep_1d(model, logtol, sweepvar, bounds, **solvek-
                                               wargs)
     Autosweep a model over one sweepvar
gpkit.tools.autosweep.get_tol(costs, bounds, sols, variable)
     Gets the intersection point and corresponding bounds from two solutions.
gpkit.tools.autosweep.recurse_splits (model, bst, variable, logtol, solvekwargs,
     Recursively splits a BST until logtol is reached
gpkit.tools.docstring module
Docstring-parsing methods
                                                                                 declara-
gpkit.tools.docstring.check_and_parse_flag(string,
                                                                      flag,
                                                         tion_func=None)
     Checks for instances of flag in string and parses them.
qpkit.tools.docstring.constant_declare(string, flag, idx2, countstr)
     Turns Variable declarations into Constant ones
```

10.1. gpkit package 77

```
gpkit.tools.docstring.expected_unbounded(instance, doc)
     Gets expected-unbounded variables from a string
class gpkit.tools.docstring.parse_variables(string, scopevars=None)
     Bases: object
     decorator for adding local Variables from a string.
     Generally called as @parse_variables(__doc__, globals()).
gpkit.tools.docstring.parse_varstring(string)
     Parses a string to determine what variables to create from it
qpkit.tools.docstring.variable_declaration (nameval, units, label, line, error-
                                                          catch=True)
     Turns parsed output into a Variable declaration
gpkit.tools.docstring.vv_declare(string, flag, idx2, countstr)
     Turns Variable declarations into VectorVariable ones
gpkit.tools.tools module
Non-application-specific convenience methods for GPkit
gpkit.tools.tools.te_exp_minus1(posy, nterm)
     Taylor expansion of e^{posy} - 1
     posy [gpkit.Posynomial] Variable or expression to exponentiate
     nterm [int] Number of non-constant terms in resulting Taylor expansion
     gpkit.Posynomial Taylor expansion of e^{posy} - 1, carried to nterm terms
gpkit.tools.tools.te_secant(var, nterm)
     Taylor expansion of secant(var).
     var [gpkit.monomial] Variable or expression argument
     nterm [int] Number of non-constant terms in resulting Taylor expansion
     gpkit.Posynomial Taylor expansion of secant(x), carried to nterm terms
gpkit.tools.tools.te_tangent(var, nterm)
     Taylor expansion of tangent(var).
     var [gpkit.monomial] Variable or expression argument
     nterm [int] Number of non-constant terms in resulting Taylor expansion
     gpkit.Posynomial Taylor expansion of tangent(x), carried to nterm terms
```

#### **Module contents**

Contains miscellaneous tools including fmincon comparison tool

#### 10.1.2 Submodules

# 10.1.3 gpkit.build module

```
Finds solvers, sets gpkit settings, and builds gpkit
class gpkit.build.CVXopt
     Bases: gpkit.build.SolverBackend
     CVXopt finder.
     look()
         Attempts to import cvxopt.
     name = 'cvxopt'
class gpkit.build.MosekCLI
     Bases: gpkit.build.SolverBackend
     MOSEK command line interface finder.
         Looks in default install locations for a mosek before version 9.
     name = 'mosek_cli'
     run (where='in the default PATH')
         Attempts to run mskexpopt.
class gpkit.build.MosekConif
     Bases: gpkit.build.SolverBackend
     MOSEK exponential cone solver finder.
         Attempts to import a mosek supporting exponential cones.
     name = 'mosek_conif'
class gpkit.build.SolverBackend
     Bases: object
     Inheritable class for finding solvers. Logs.
     look = None
     name = None
gpkit.build.build()
     Builds GPkit
gpkit.build.call(cmd)
     Calls subprocess. Logs.
gpkit.build.diff (filename, diff_dict)
     Applies a simple diff to a file. Logs.
gpkit.build.isfile(path)
     Returns true if there's a file at $path. Logs.
qpkit.build.log(*args)
     Print a line and append it to the log string.
gpkit.build.pathjoin(*args)
     Join paths, collating multiple arguments.
```

```
gpkit.build.replacedir(path)
    Replaces directory at $path. Logs.
10.1.4 gpkit.exceptions module
GPkit-specific Exception classes
exception gpkit.exceptions.DualInfeasible
     Bases: gpkit.exceptions.Infeasible
     Raised if a model returns a certificate of dual infeasibility
exception gpkit.exceptions.Infeasible
     Bases: RuntimeWarning
     Raised if a model does not solve
exception gpkit.exceptions.InvalidGPConstraint
     Bases: gpkit.exceptions.MathematicallyInvalid
     Raised if a non-GP-compatible constraint is used in a GP
exception gpkit.exceptions.InvalidLicense
     Bases: RuntimeWarning
     Raised if a solver's license is missing, invalid, or expired.
exception gpkit.exceptions.InvalidPosynomial
    Bases: gpkit.exceptions.MathematicallyInvalid
     Raised if a Posynomial would be created with a negative coefficient
exception gpkit.exceptions.InvalidSGPConstraint
     Bases: gpkit.exceptions.MathematicallyInvalid
     Raised if a non-SGP-compatible constraint is used in an SGP
exception gpkit.exceptions.MathematicallyInvalid
    Bases: TypeError
    Raised whenever something violates a mathematical definition.
exception gpkit.exceptions.PrimalInfeasible
    Bases: gpkit.exceptions.Infeasible
     Raised if a model returns a certificate of primal infeasibility
exception gpkit.exceptions.UnboundedGP
    Bases: ValueError
     Raise if a GP is not fully bounded
exception gpkit.exceptions.UnknownInfeasible
     Bases: gpkit.exceptions.Infeasible
```

Raised if a model does not solve for unknown reasons

exception gpkit.exceptions.UnnecessarySGP

Raised if an SGP is fully GP-compatible

Bases: ValueError

## 10.1.5 gpkit.globals module

```
global mutable variables
```

```
class gpkit.globals.NamedVariables(name)
    Bases: object
```

Creates an environment in which all variables have a model name and num appended to their varkeys.

```
lineage = ()
modelnums = {((), 'SGP'): 1}
namedvars = {}
classmethod reset modelnumbers()
```

Clear all model number counters

```
class gpkit.globals.SignomialsEnabled
    Bases: object
```

Class to put up and tear down signomial support in an instance of GPkit.

```
>>> import gpkit
>>> x = gpkit.Variable("x")
>>> y = gpkit.Variable("y", 0.1)
>>> with SignomialsEnabled():
>>> constraints = [x >= 1-y]
>>> gpkit.Model(x, constraints).localsolve()
```

```
class gpkit.globals.SignomialsEnabledMeta
```

Bases: type

Metaclass to implement falsiness for SignomialsEnabled

```
class gpkit.globals.Vectorize(dimension_length)
    Bases: object
```

Creates an environment in which all variables are exended in an additional dimension.

```
vectorization = ()
```

```
gpkit.globals.load_settings (path=None, trybuild=True)
    Load the settings file at SETTINGS_PATH; return settings dict
```

## 10.1.6 gpkit.keydict module

Implements KeyDict and KeySet classes

```
class gpkit.keydict.KeyDict(*args, **kwargs)
    Bases: gpkit.keydict.KeyMap, dict
```

KeyDicts do two things over a dict: map keys and collapse arrays.

```
>>> kd = gpkit.keydict.KeyDict()
```

For mapping keys, see KeyMapper.\_\_doc\_\_

If .collapse\_arrays is True then VarKeys which have a *shape* parameter (indicating they are part of an array) are stored as numpy arrays, and automatically de-indexed when a matching VarKey with a particular *idx* parameter is used as a key.

```
See also: gpkit/tests/t_keydict.py.

collapse_arrays = True

get (key, *alternative)
    Return the value for key if key is in the dictionary, else default.

update (*args, **kwargs)
    Iterates through the dictionary created by args and kwargs
```

```
class gpkit.keydict.KeyMap(*args, **kwargs)
    Bases: object
```

Helper class to provide KeyMapping to interfaces.

A KeyMap keeps an internal list of VarKeys as canonical keys, and their values can be accessed with any object whose *key* attribute matches one of those VarKeys, or with strings matching any of the multiple possible string interpretations of each key:

For example, after creating the KeyDict kd and setting kd[x] = v (where x is a Variable or VarKey), v can be accessed with by the following keys:

- X
- · x.key
- x.name (a string)

*kit.ureg.m*}) are equivalent.

• "x\_modelname" (x's name including modelname)

Note that if a item is set using a key that does not have a .key attribute, that key can be set and accessed normally.

```
collapse_arrays = False
     keymap = []
     log_gets = False
     parse_and_index(key)
         Returns key if key had one, and veckey/idx for indexed veckeys.
     update_keymap()
          Updates the keymap with the keys in unmapped keys
     varkeys = None
class gpkit.keydict.KeySet(*args, **kwargs)
     Bases: gpkit.keydict.KeyMap, set
     KeyMaps that don't collapse arrays or store values.
     collapse arrays = False
     update (keys)
         Iterates through the dictionary created by args and kwargs
gpkit.keydict.clean_value(key, value)
     Gets the value of variable-less monomials, so that x.sub(x: gpkit.units.m) and x.sub(x: gp-instance)
```

Also converts any quantities to the key's units, because quantities can't/shouldn't be stored as elements of numpy arrays.

## 10.1.7 gpkit.repr conventions module

```
Repository for representation standards
class gpkit.repr_conventions.ReprMixin
     Bases: object
     This class combines various printing methods for easier adoption.
     ast = None
     cached_strs = None
     latex unitstr()
          Returns latex unitstr
     lineagestr (modelnums=True)
          Returns properly formatted lineage string
     parse_ast (excluded='units')
          Turns the AST of this object's construction into a faithful string
     unitstr(into='%s', options=':P~', dimless=")
          Returns the string corresponding to an object's units.
gpkit.repr_conventions.latex_unitstr(units)
     Returns latex unitstr
qpkit.repr_conventions.lineagestr(lineage, modelnums=True)
     Returns properly formatted lineage string
gpkit.repr_conventions.parenthesize(string, addi=True, mult=True)
     Parenthesizes a string if it needs it and isn't already.
gpkit.repr conventions.strify(val, excluded)
     Turns a value into as pretty a string as possible.
gpkit.repr_conventions.unitstr(units, into='%s', options=':P~', dimless=")
     Returns the string corresponding to an object's units.
10.1.8 gpkit.small_classes module
Miscellaneous small classes
class gpkit.small_classes.CootMatrix(row, col, data)
     Bases: object
     A very simple sparse matrix representation.
     dot (arg)
          Returns dot product with arg.
          Converts to another type of matrix.
     tocsc()
          Converts to another type of matrix.
```

10.1. gpkit package

todense()

Converts to a Scipy sparse csr\_matrix

Converts to another type of matrix.

```
todia()
          Converts to another type of matrix.
     todok()
          Converts to another type of matrix.
class gpkit.small_classes.Count
     Bases: object
     Like python 2's itertools.count, for Python 3 compatibility.
          Increment self.count and return it
class gpkit.small_classes.DictOfLists
     Bases: dict
     A hierarchy of dicionaries, with lists at the bottom.
     append(sol)
          Appends a dict (of dicts) of lists to all held lists.
     atindex(i)
          Indexes into each list independently.
     to_arrays()
          Converts all lists into array.
class gpkit.small_classes.FixedScalar
     Bases: object
     Instances of this class are scalar Nomials with no variables
class gpkit.small_classes.FixedScalarMeta
     Bases: type
     Metaclass to implement instance checking for fixed scalars
class gpkit.small_classes.HashVector
     Bases: dict
     A simple, sparse, string-indexed vector. Inherits from dict.
     The HashVector class supports element-wise arithmetic: any undeclared variables are assumed to
     have a value of zero.
     arg: iterable
     >>> x = gpkit.nomials.Monomial("x")
     >>> exp = gpkit.small_classes.HashVector({x: 2})
     copy()
          Return a copy of this
     hashvalue = None
class gpkit.small_classes.SolverLog(output=None, *, verbosity=0)
     Bases: list
     Adds a write method to list so it's file-like and can replace stdout.
     write(writ)
          Append and potentially write the new line.
```

```
gpkit.small_classes.matrix_converter(name)
Generates conversion function.
```

## 10.1.9 gpkit.small\_scripts module

```
Assorted helper methods
```

```
qpkit.small scripts.appendsolwarning(msg,
                                                          data,
                                                                     result,
                                                                                 cate-
                                                gory='uncategorized')
     Append a particular category of warnings to a solution.
gpkit.small_scripts.is_sweepvar(sub)
     Determines if a given substitution indicates a sweep.
gpkit.small\_scripts.mag(c)
     Return magnitude of a Number or Quantity
gpkit.small_scripts.maybe_flatten(value)
     Extract values from 0-d numpy arrays, if necessary
gpkit.small_scripts.splitsweep(sub)
     Splits a substitution into (is_sweepvar, sweepval)
gpkit.small_scripts.try_str_without (item, excluded, *, latex=False)
     Try to call item.str without(excluded); fall back to str(item)
```

## 10.1.10 gpkit.solution\_array module

Defines SolutionArray class

```
class gpkit.solution_array.SolSavingEnvironment(solarray)
    Bases: object
```

Temporarily removes construction/solve attributes from constraints.

This approximately halves the size of the pickled solution.

```
class gpkit.solution_array.SolutionArray
    Bases: gpkit.small_classes.DictOfLists
```

A dictionary (of dictionaries) of lists, with convenience methods.

cost: array variables: dict of arrays sensitivities: dict containing:

monomials: array posynomials: array variables: dict of arrays

localmodels [NomialArray] Local power-law fits (small sensitivities are cut off)

```
>>> import gpkit
>>> import numpy as np
>>> x = gpkit.Variable("x")
>>> x_min = gpkit.Variable("x_{min}", 2)
>>> sol = gpkit.Model(x, [x >= x_min]).solve(verbosity=0)
>>>
>>> # VALUES
>>> values = [sol(x), sol.subinto(x), sol["variables"]["x"]]
>>> assert all(np.array(values) == 2)
>>>
>>> # SENSITIVITIES
```

(continues on next page)

(continued from previous page)

```
>>> senss = [sol.sens(x_min), sol.sens(x_min)]
>>> senss.append(sol["sensitivities"]["variables"]["x_{min}"])
>>> assert all(np.array(senss) == 1)
almost equal (other, reltol=0.001, sens abstol=0.01)
     Checks for almost-equality between two solutions
static decompress file (file)
     Load a gzip-compressed pickle file
diff (other, showvars=None, *, constraintsdiff=True, senssdiff=True, sensstol=0.1, absd-
       iff=False, abstol=0, reldiff=True, reltol=1.0, **tableargs)
     Outputs differences between this solution and another
     other [solution or string] strings will be treated as paths to pickled solutions
     senssdiff [boolean] if True, show sensitivity differences
     sensstol [float] the smallest sensitivity difference worth showing
     abssdiff [boolean] if True, show absolute differences
     absstol [float] the smallest absolute difference worth showing
     reldiff [boolean] if True, show relative differences
     reltol [float] the smallest relative difference worth showing
     str
modelstr = ''
name_collision_varkeys()
     Returns the set of contained varkeys whose names are not unique
plot (posys=None, axes=None)
     Plots a sweep for each posy
save (filename='solution.pkl', **pickleargs)
     Pickles the solution and saves it to a file.
                                   loaded
     Solution
                       then
                              be
                                                                                pickle
                                                                                       >>>
                can
                                             with
                                                     e.g.:
                                                                      import
     pickle.load(open("solution.pkl"))
save_compressed (filename='solution.pgz', **cpickleargs)
     Pickle a file and then compress it into a file with extension.
savecsv (showvars=None, filename='solution.csv', valcols=5)
     Saves primal solution as a CSV sorted by modelname, like the tables.
savemat (filename='solution.mat', showvars=None, excluded=('unnecessary lineage',
            'vec'))
     Saves primal solution as matlab file
savetxt (filename='solution.txt', printmodel=True, **kwargs)
     Saves solution table as a text file
subinto(posy)
     Returns NomialArray of each solution substituted into posy.
summary (showvars=(), ntopsenss=5, **kwargs)
     Print summary table, showing top sensitivities and no constants
```

```
table (showvars=(), tables=('cost', 'warnings', 'sweepvariables', 'freevariables', 'con-
             stants', 'sensitivities', 'tightest constraints'), **kwargs)
          A table representation of this SolutionArray
          tables: Iterable
              Which to print of ("cost", "sweepvariables", "freevariables", "constants", "sensitiv-
                  ities")
          fixedcols: If true, print vectors in fixed-width format latex: int
              If > 0, return latex format (options 1-3); otherwise plain text
          included_models: Iterable of strings If specified, the models (by name) to include
          excluded_models: Iterable of strings If specified, model names to exclude
     table_titles = {'constants':
                                              'Fixed Variables', 'freevariables':
                                                                                               'Free Variables
     todataframe (showvars=None, excluded=('unnecessary lineage', 'vec'))
          Returns primal solution as pandas dataframe
     varnames (showvars, exclude)
          Returns list of variables, optionally with minimal unique names
gpkit.solution_array.cast (function, val1, val2)
     Relative difference between val1 and val2 (positive if val2 is larger)
gpkit.solution_array.constraint_table (data, title, sortbymodel=True, showmod-
                                                   els=True, **)
     Creates lines for tables where the right side is a constraint.
gpkit.solution_array.insenss_table(data, _, maxval=0.1, **kwargs)
     Returns insensitivity table lines
gpkit.solution_array.loose_table (self, _, min_senss=le-05, **kwargs)
     Return constraint tightness lines
qpkit.solution_array.senss_table (data, showvars=(), title='Variable Sensitivities',
                                            **kwargs)
     Returns sensitivity table lines
gpkit.solution_array.tight_table(self, _, ntightconstrs=5, tight_senss=0.01,
                                            **kwargs)
     Return constraint tightness lines
gpkit.solution_array.topsenss_filter(data, showvars, nvars=5)
     Filters sensitivities down to top N vars
gpkit.solution_array.topsenss_table(data, showvars, nvars=5, **kwargs)
     Returns top sensitivity table lines
gpkit.solution_array.unrolled_absmax(values)
     From an iterable of numbers and arrays, returns the largest magnitude
gpkit.solution_array.var_table (data, title, *, printunits=True, latex=False, raw-
                                         lines=False, varfmt='%s: ', valfmt='%-.4g',
                                         vecfmt='\%-8.3g', minval=0, sortbyvals=False,
                                         hidebelowminval=False, included_models=None,
                                         excluded models=None, sortbymodel=True, max-
                                         columns=5, skipifempty=True, **_)
```

10.1. gpkit package 87

```
Pretty string representation of a dict of VarKeys Iterable values are handled specially (partial print-
     ing)
      data [dict whose keys are VarKey's] data to represent in table
      title: string printunits: bool latex: int
           If > 0, return latex format (options 1-3); otherwise plain text
      varfmt [string] format for variable names
     valfmt [string] format for scalar values
      vecfmt [string] format for vector values
      minval [float] skip values with all(abs(value)) < minval
     sortbyvals [boolean] If true, rows are sorted by their average value instead of by name.
     included_models [Iterable of strings] If specified, the models (by name) to include
      excluded_models [Iterable of strings] If specified, model names to exclude
gpkit.solution_array.warnings_table (self, _, **kwargs)
      Makes a table for all warnings in the solution.
10.1.11 gpkit.units module
wraps pint in gpkit monomials
      Bases: object
      Return Monomials instead of Quantitites
```

```
class gpkit.units.GPkitUnits
    Bases: object

Return Monomials instead of Quantitites

division_cache = {}

monomial_cache = {}

multiplication_cache = {}

of_division (numerator, denominator)
    Cached unit division. Requires Quantity inputs.

of_product (thing1, thing2)
    Cached unit division. Requires united inputs.

gpkit.units.qty (unit)
```

# 10.1.12 gpkit.varkey module

Defines the VarKey class

```
class gpkit.varkey.VarKey(name=None, **descr)
    Bases: gpkit.repr_conventions.ReprMixin
    An object to correspond to each 'variable name'.
```

Returns a Quantity, caching the result for future retrievals

\*\*descr: Any additional attributes, which become the descr attribute (a dict).

**name** [str, VarKey, or Monomial] Name of this Variable, or object to derive this Variable from.

```
VarKey with the given name and descr.
latex (excluded=())
    Returns latex representation.

models
    Returns a tuple of just the names of models in self.lineage
str_without (excluded=())
    Returns string without certain fields (such as 'lineage').
subscripts = ('lineage', 'idx')
classmethod unique_id()
    Increment self.count and return it
vars_of_a_name = {}
```

#### 10.1.13 Module contents

GP and SP modeling package

10.1. gpkit package

# CHAPTER 11

Citing GPkit

If you use GPkit please cite it with the following bibtex:

(and you can read that paper, which describes some of GPkit's design philosophy, here.)

# CHAPTER 12

# Acknowledgements

We thank the following contributors for helping to improve GPkit:

- Marshall Galbraith for setting up continuous integration.
- Stephen Boyd for inspiration and suggestions.
- Kirsten Bray for designing the GPkit logo.

# CHAPTER 13
